Our idea:

- Grinding discarded tree residues in a special mill to turn them into arable soil.
- Allocating bags of certain colors to plastic and glass for easy classification later (Like red for glass and green for plastic).
- The rest of the garbage is thrown in one place as usual and disposed of by burning in a machine dedicated to generating energy, and that energy is used to run the tree mill.
- Allocate a container for leftovers next to the well-known garbage container, and what is inside is collected daily, dried in the appropriate way, and then ground to make it an organic alternative to animal food.
